Introduction

Punios šilas nature reserve (further Punios šilas) is located in the central part of Lithuania within the large loop formed by the river Nemunas. Unfragmented mixed forest covers undulating terrain. The uniqueness of this forest is the fact that commercial management was not intensive for at least several hundred years. Therefore, a decision was made to establish it as a botanical - zoological preserve in 1960. Additionally, a strict nature reserve was established in 4.2 sq. km. of the area at that time. Thanks to the efforts of numerous naturalists and nature researchers, the status of the botanical-zoological preserve was changed to the strict nature reserve in 2022, which currently covers an area of about 24 square kilometres. Although Punios šilas has exceptional value from a biodiversity point of view as a preserved old-growth natural forest with the highest abundance of protected species and ecosystem components in Lithuania, the studies of Coleoptera in this area were fragmental in the past. The published information of some records of rare beetle species is scattered among lots of faunistic papers (Ferenca, 2004; Ivinskis *et al.*, 2007, 2009; Tamutis *et al.*, 2010, 2015, 2019; Bukejs *et al.*, 2012; Ferenca *et al.*, 2018; Tamutis & Alekseev, 2020; Davenis *et al.*, 2022; Jaskula *et al.*, 2024).

Under the project the LIFE-IP-NATURALIT "Optimizing the management of Natura 2000 network in Lithuania" was planned to start multi-taxa forest monitoring including beetles in this unique area. Beetle monitoring was focused on determination of the structure of decaying wood-related (saproxylic) beetle assemblages, as one of the best bioindicators in this type of ecosystem, at pre-selected monitoring points.

This study presents the most interesting discoveries of beetles made during the first stage of beetle monitoring in the Punios šilas nature reserve.

Material and Methods

The majority of the material was collected by flight interception traps (FIT) in 2023 (Fig. 2). Altogether, 50 traps were installed in half of the territory of Punios šilas nature reserve at the specially selected monitoring places (marked with numbers and red dots on the map, Figure 1), which have been operating since May 19 till July 21, 2023. Additionally, herein we include the interesting discoveries of beetles made during previous studies or sampled using handling (HD) (marked with Latin letters and yellow dots on the

map). To include the beetle species in this paper, we applied the following criteria: 1) species classified as very rare or rare for Lithuanian fauna according to Pileckis and Monsevičius (1995, 1997); 2) species with actual faunistic information (containing exact

The map of Lithuania is gridded using borders of administrative units (mun.) according to the document by the Government of the Republic of Lithuania, “Order of administrative units and its borders of the Republic of Lithuania” Order I–558 from July 19, 1994 (www.e-tar.lt/portal/lt/legalAct/TAR.0120FD7BCFFC/ZhxPsGFEbL). The territories of Birštonas, Kaunas town, Vilnius town, and Visaginas mun. were merged with territories of surrounding administrative units (district mun.) on the map in the following order: Birštonas - with Prienai District, Kaunas town - with Kaunas District, Vilnius town – with Vilnius District, and Visaginas – with Ignalina district mun.

*****Denticollis borealis (Paykull, 1800)***

Records: [22], I, FIT, (1), V.T. (Fig.5, A).

Remarks. External morphological characters of specimen we discovered are consistent with the description of this species given by Tarnawski & Buchholz (2010). This species has a Trans-Eurasian-Boreo-Mountain type of distribution range and is considered as a primeval forest relict beetle species (Eckelt *et al.*, 2018). The northern border of its distribution range reaches northern provinces of Fennoscandia and European Russia: (Olberg *et al.*, 2001; Rassi *et al.*, 2015). It is extremely rare in Central Europe (Eckelt *et al.*, 2018). The nearest discoveries of this species are from Latvia (Barševskis, 2005) and Belarus (Aleksandrowich *et al.*, 2023).

*****Pseudanostirus globicollis* (Germar, 1842)**

Records: [22], I, FIT, (1), V.T., (Fig. 5, B).

Remarks. External morphological characters of specimen we discovered is consistent with the description of this species given by Tarnawski & Buchholz (2008). This rare European species prefers natural deciduous and mixed forests; however, its biology is insufficiently known (Buchholz & Burakowski, 1992). It is recorded from Finland (Rassi *et al.*, 2015), but still not known in rest of Fennoscandia, Estonia and Latvia (Cate, 2007). The nearest discoveries of this species are from Belarus (Aleksandrowich *et al.*, 2023) and Poland (Tarnawski & Buchholz, 2008).

EUCNEMIDAE

*****Clypeorhagus clypeatus* (Hampe, 1850)**

Records: [91], II, III, FIT, (1, 4), V.T., (Fig. 6).

Remarks. External morphological characters of specimens we discovered are consistent with the description of this species given by Burakowski (1991). This saproxylic species is rare and insufficiently known. Though it was noted just from a dozen of countries in Europe (Muona, 2007; Mertlik *et al.*, 2007; Süda, 2009b; Solodovnikov & Solodovnikova, 2019), the discoveries of this species in Far East (Mertlik *et al.*, 2007) and Iran (Jarzabek-Müller, 2019) suggest much wider its distribution range. The nearest discoveries of this species are from Latvia (Telnov, 2004) Belarus (Solodovnikov & Solodovnikova, 2019) and Poland (Burakowski, 1991).

*****Hylis olexai* (Palm, 1955)**

Records: [21, 30, 55, 67, 68, 69, 70, 79, 91, 94, 97], III, FIT, (1, 1, 1, 2, 1, 1, 1, 1, 8, 1, 1), V.T. (Fig. 7).

Remarks. External morphological characters of specimens we discovered are consistent with the description of this species given by Burakowski (1991). This species relatively recently described and still is known in Europe from Great Britain and Spain to Volga region (European Russia) (Volodchenko & Sazhnev, 2023);

the northern extent of its distribution range goes through the southern Finland and Karelia (Clayhills, 2014), in the South it goes to Croatia and Bosnia and Herzegovina (Muona, 2007; Mertlik & Pelikan, 2013). The nearest discoveries of this species are from Latvia (Telnov, 2004) Kaliningrad Region (Alekseev *et al.*, 2021) and Poland (Hilszczański *et al.*, 2015).

Records: [21, 22, 32, 43, 69, 83], II, FIT, (1, 1, 20, 1, 1, 4), V.T.; [2, 3, 11, 22, 32, 33, 34, 42, 43, 45, 46, 57, 58, 67, 69, 70, 83, 93, 94] III, FIT, (1, 1, 1, 2, 41, 3, 9, 1, 12, 2, 1, 12, 7, 1, 4, 10, 16, 10, 3), V.T., (Fig. 8).

Remarks. External morphological characters of specimens we discovered are consistent with the description of this species given by Burakowski (1991). This species is known in Europe from Norway to Northern Caucasus (Dagestan) (Bibin, 2020); the northern border of its distribution range goes through the Estonia (Roosileht, 1994), to the South it goes to the Bosnia and Herzegovina (Muona, 2007). The nearest discoveries of this species are from Latvia (Telnov, 2004) Kaliningrad Region (Aleksiev, 2020) and Poland (Hilszczański *et al.*, 2015).

***Hydrobius subrotundus* Stephens, 1829

Records: [19], I, FIT, (1), V.T., (Fig. 9).

Remarks. For long time this taxon was regarded as morphological variation of *Hydrobius fuscipes* (Linnaeus, 1758) until detailed analysis has been carried out and its status was elevated to valid species (Fossen *et al.*, 2016). Unfortunately, we trapped a single specimen (female) of this species and couldn't confirm the morphological identity using characters of male genitalia. However, black color of legs (Fig. 9) fully fit to description of *H. subrotundus* according Fossen *et al.* (2016). Distribution range of the species still unclear, currently it is known from Fennoscandia and Central Europe (Fossen *et al.*, 2016)

LEIODIDAE

*****Agathidium (Cyphocele) discoideum* Erichson, 1845**

Records: [91], I, FIT, (1), V.T.; [70], II, FIT, (1), V.T., (Fig. 10).

Remarks. External morphological characters and structures of genitalia of specimens we discovered are consistent with the description of this species given by Kilian & Borowiec (1998). This species is considered to have a boreomontane distribution range in the Palaearctic realm, is recorded in Europe, Far East and Mongolia (Perreau, 2004). The northern border of its distribution range reaches northern provinces of Fennoscandia and European Russia: Lule Loppmark, Kittilän Lappi, Siktivkar (Lundberg & Gustafsson, 1995; Rassi *et al.* 2015; Ishkaeva & Nikitsky, 2017), however in Central and Southern Europe this species is known mainly from mountainous areas (Angelini, 1995). The nearest discoveries of this species are from Białowieża Forest (Poland) (Kilian & Borowiec, 1998) and Belarus (Aleksandrowich *et al.*, 2023).

***Dorcatoma* (*Pilosodorcatoma*) *janssoni* Büche & Lundberg, 2002

Records: [13, 30, 91], II, FIT, (1, 1, 1), V.T.; [22, 41, 57, 58, 91], III, FIT, (1, 1, 1, 1, 1), V.T. (Fig. 14).

Remarks. External morphological characters of specimens we discovered are consistent with the original description of this species (Büche & Lundberg, 2002). This species relatively recently described and its distribution still is poorly known. To this moment this species was recorded only from five European countries: Estonia, Latvia, Sweden, Belarus and Poland (Büche & Lundberg, 2002; Süda & Voolma, 2007; Aleksandrowich *et al.*, 2023).

***Dorcatoma* (*Pilosodorcatoma*) *substriata* Hummel, 1829

Records: [31, 91], II, FIT, (2, 2), V.T., (Fig. 15).

Remarks. External morphological characters of specimens we discovered are consistent with the description of this species given by Baranowski (1985). This species is widespread in Europe from Great Britain and Spain to central part of European Russia (Borowski & Zahradnik, 2007; Nikitsky & Schigel, 2004); the northern border of its distribution reach Pohjois-Savon province in Finland (Rassi *et al.*, 2015), to the South it goes to Croatia (Zahradnik, 2007).

The nearest discoveries of this species are from Poland (Borowski, 2001) and Belarus

(Aleksandrowich *et al.*, 2023).

Discussion

The information on 5880 specimens belonging to 30 species and 55 families of Coleoptera is presented in this paper. Our research revealed 293 beetle species new for the fauna of Punios šilas nature reserve, of which 18 are new to the fauna of Lithuania. The information only on 31 beetle species detected in Punios šilas has been reported previously (Bukejs *et al.*, 2012; Davenis *et al.* 2022; Ferenca, 2004; Ferenca & Tamutis, 2015; Ferenca *et al.* 2018; Ivinskis *et al.*, 2007, 2009) Tamutis & Alekseev, 2020; Tamutis *et al.*, 2010, 2015, 2019), of which six species, namely *Calosoma inquisitor* (Linnaeus, 1758), *Ceruchus chrysomelinus* (Hochenwart, 1785), *Osmoderma barnabita* Motschulsky 1845, *Protaetia lugubris* (Herbst, 1786) = *Protaetia (Liocola) marmorata marmorata* (Fabricius, 1792), *Peltis grossa* (Linnaeus, 1758), and *Necydalis major* Linnaeus, 1758 are officially protected (Rašomavičius, 2021). Additionally two more protected species were discovered during current studies: *Cucujus cinnaberinus* (Scopoli, 1763) and *Dendroxena quadrimaculata* (Scopoli, 1771).

The discovery of large number of rare or insufficiently known and new for Lithuanian fauna beetle's species is explained by the intensive trapping and high diversity of forest types. A comparatively large number (>50) of flight interception traps have been used in high diversities of forest types, altogether 11 types (Table 1), of the forest stands during the period of highest activity of beetles (May – June). Using this method were sampled 5862 individuals of selected species, however some of rare species, such as: *Agabus* (s. str.) *undulatus*, *Badister (Trimophus) sodalis*, *Bembidion (Diplocampa) assimile*, *Bembidion (Semicampa) schueppelii*, *Dyschirius (Dyschiriodes) nitidus nitidus*, *Dyschirius* (s. str.) *thorasicus*, *Dytiscus dimidiatus*, *Epuraea* (s. str.) *guttata*, *Oxyporus mannerheimi*, *Tanysphyrus lemnae* were discovered searching in its suitable microhabitats.

It is interesting to note that different traps caught a different number of selected beetle species in the study area (Fig. 19), which corresponds the value of stand from a biodiversity point of view. The highest number (>60) of species were discovered in 13, 30, 44, 91, and 93 monitoring points corresponding different types of mature forest with some gaps: *Myrtillo – Pinetum*, *Vaccinio – Myrtillo – Pinetum*, *Oxalido – nemoroso – Piceetum* and *Carico – sphagnum Pinetum* (Fig. 20). On another hand a lowest number (<30) of species were discovered in 9, 12, 20, 57, and 58 monitoring points, with relatively young and dense stands (Fig. 21).

The exceptional value of the Punia šilas forest is indicated by the species discovered during this study, such as: *Ampedus elongatulus*, *Corticeus* (s. str.) *suturalis*, *Denticollis borealis*, *Leiestes seminiger*, *Mycetophagus* (s. str.) *ater*, *Otho spondyloides*, *Peltis grossa*, *Phryganophilus* (s. str.) *auritus*, *Platylomalus complanatus*, *Stagetus borealis*, and *Stictoleptura (Varileptura) vairicornis*. These species are considered as relicts of the primeval forests of Central Europe (Eckelt *et al.*, 2018).

Įdomūs vabalų (Insecta: Coleoptera) rūšių faunistiniai atradimai Punios šilo gamtiniame rezervate – seniausiam Lietuvos miške.

Santrauka

Punios šilas yra išskirtinės vertės medynų kompleksas, kuriame dėl ribojamos ūkinės veiklos išliko daug pirmykščiems Europos miškams būdingų gamtinių komponentų. Šioje unikalioje teritorijoje vykdamas projektą LIFE-IP PAF-NATURALIT „Natura 2000 tinklo valdymo optimizavimas Lietuvoje“ buvo atlikti ir vabalų bendrijų tyrimai. Punios šilo gamtinio rezervato teritorijoje sistemingai numatytose tyrimų vietose buvo įrengtos specialios skrydį trikdančios vabalų gaudyklės. Šiame straipsnyje pateikiama informacija apie retų, mažai žinomų ir naujų Lietuvos faunai vabalų (Coleoptera) rūšių aptikimo duomenis gautus išanalizavus 2023 metais, gegužės – liepos mėnesiais, 50 gaudyklių surinktą medžiagą. Taip pat pateikiama informacija apie naujas Punios šilo gamtinio rezervato faunai vabalų rūšis aptiktas ankstesnių tyrimų metu. Iš viso buvo pateikta informacija apie 5880 individų priklausančių 302 rūšims ir 55 vabalų būrio šeimoms aptikimo faktus Punios šilo gamtiniame rezervate. Iš jų 18 rūšių yra naujos Lietuvos faunai: *Agathidium discoideum* Erichson *Atomaria ornata* Heer, *Aulanothroscus laticollis* (Rybinski), *Clypeorhagus clypeatus* (Hampe), *Colon barnevillei* Kraatz, *Denticollis borealis* (Paykull), *Dorcatoma janssoni* Büche & Lundberg, *D. substriata* Hummel, *D. punctulata* Mulsant & Rey, *Erotides cosnardi* (Chevrolat), *Hylis olexai* (Palm), *Hydrobius subrotundus* Stephens, *Isorhipis marmottani* Bovouloir, *Mordellaria aurofasciata* (Comolli), *Mordellistena neuwaldeggiana* (Panzer), *Pseudanostirus globicollis* (Germar), *Rhyncolus punctatulus* Boheman, *Stagetus borealis* Israelson. Kai kurių pirmykščių miškų reliktnių rūšių, tokių kaip: *Ampedus elongatulus*, *Corticeus suturalis*, *Denticollis borealis*, *Leiastes seminiger*, *Mycetophagus ater*, *Otho spondyloides*, *Peltis grossa*, *Phryganophilus auritus*, *Platylomalus complanatus*, *Stagetus borealis* ir *Stictoleptura variicornis* aptikimas Punios šilo gamtiniame rezervate byloja apie išskirtinę jo vertę bioįvairovės požiūriu.
